Architectural Views

1. Logical View

The following package diagram can be considered a logical view as it emphasizes the logical relationships and dependencies between different components or modules of the system, without delving into the physical aspects or implementation details.

Package Diagram

The following package diagram of the SAMS2024 system provides a high-level view of the organization and structuring of a system. The system here is broken down into manageable components, promoting modularity and making it easier to understand the system communications/relationships.

2. Use Case View (+1)

In the "[Detailed Requirements Model using Use Cases](#)" document, the team thoroughly described individual use cases, including their preconditions, main flow, alternative scenarios, and postconditions. This comprehensive detailing ensured a clear and unambiguous understanding of how the system should function from a user's perspective.

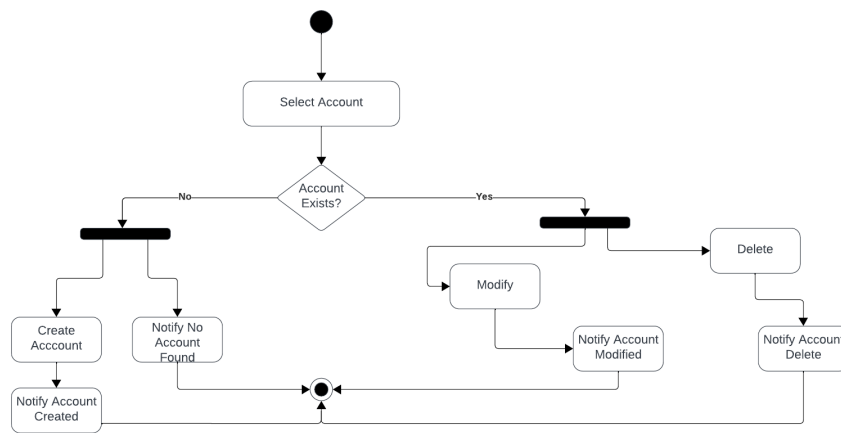

3. Process View

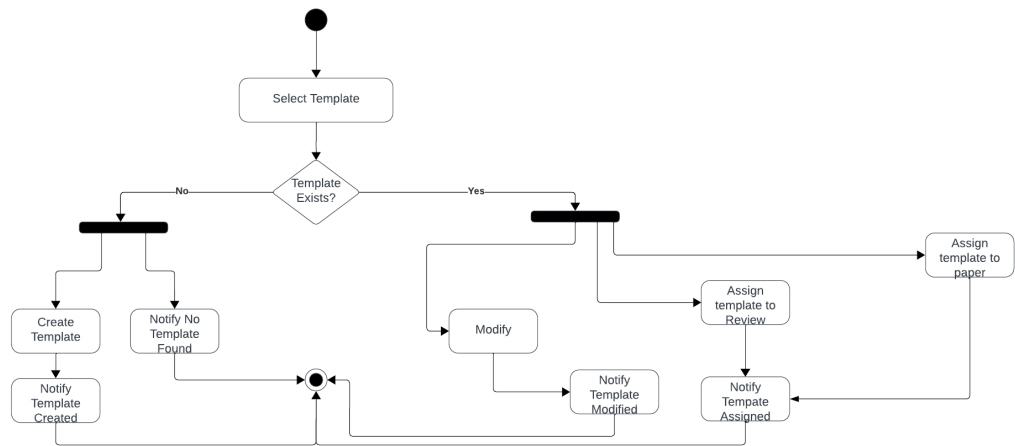

The following process view/flow diagrams illustrate how system components interact over time, providing insights into the system's behavior, flow of data, and control between processes. The process diagrams are divided among the different actors/users involved in the system.
